

CSS422 Final Project

Thumb-2 Implementation Work of Memory -Related C Standard Library Functions.

Disclaim: This project is modified based on Professor Munehiro Fukuda's project design.

Last Updated Date: 10/20/2022

Updates: Updated explanations and instructions about provided template files.

1. Objective

Through this final project, you will implement memory-related C standard library functions using Thumb-

2. You'll understand the following concepts at the ARM assembly language level:

- CPU operating modes: user and supervisor modes
- System-call handling procedures
- C to assembler argument passing (APCS: ARM Procedure Call Standard)
- Stack operations to implement recursions at the assembly language level
- Buddy memory allocation

2. Project Overview

Using the Thumb-2 assembly language, you will implement four functions of the C standard library (See **Table 1**) that will be invoked from a C program named `driver.c`. You will use a provided file, `driver_keil.c` to test your implementation. **These functions must be coded in the Thumb-2 assembly language.** Some of them can be implemented in `stdli.s` running in the unprivileged thread mode (user mode), whereas the others need to be implemented as supervisor calls, i.e., in the handler mode (= supervisor mode).

For more details, log in one of the CSS Linux servers and type from the Linux shell:

`man 3 functionName` where *functionName* is `bzero`, `strncpy`, `malloc`, or `free`.

Table 1: C standard lib functions to be implemented in the final project

C standard lib functions	In <code>stdli.s</code> *1	As SVC *2
<code>bzero(void *s, size_t n)</code> writes <u>n</u> zeroed bytes to the string <u>s</u> . If <u>n</u> is zero, <code>bzero()</code> does nothing. https://man7.org/linux/man-pages/man3/bzero.3.html	Yes	
<code>strncpy(char *dst, const char *src, size_t num)</code> copies at most <u>num</u> characters from <u>src</u> into <u>dst</u> . It returns <u>dst</u> . https://man7.org/linux/man-pages/man3/strncpy.3p.html	Yes	
<code>malloc(size_t size)</code> allocates <u>size</u> bytes of memory and returns a pointer to the allocated memory. If successful, it returns a pointer to allocated memory. Otherwise, it returns a NULL pointer. https://man7.org/linux/man-pages/man3/malloc.3p.html		Yes
<code>free(void *ptr)</code> Deallocates the memory allocation pointed to by <u>ptr</u> . If <u>ptr</u> is a NULL pointer, no operation is performed. If successful, it returns a pointer to allocated memory. Otherwise, it returns a NULL pointer. https://man7.org/linux/man-pages/man3/free.3p.html		Yes

*1: To be implemented in `stdli.s` in the unprivileged thread mode

*2: To be passed as an SVC to SVC_Handler in the privileged handler mode

The `driver.c` we use is shown in *Listing 1*. It tests all the above four functions. Please note that `printf()` in the code should be removed when you test your assembly implementation, because we won't implement the `printf()` standard function.

Listing 1: `driver.c` program to understand how the required functions work

```
#include <strings.h> // bzero, strncpy
#include <stdlib.h> // malloc, free
#include <stdio.h> // printf

int main() {
    char stringA[40] = "0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZabc\0";
    char stringB[40];

    bzero( stringB, 40 );
    strncpy( stringB, stringA, 40 );
    bzero( stringA, 40 );
    printf( "%s\n", stringA );
    printf( "%s\n", stringB );

    void* mem1 = malloc( 1024 );
    void* mem2 = malloc( 1024 );
    void* mem3 = malloc( 8192 );
    void* mem4 = malloc( 4096 );
    void* mem5 = malloc( 512 );
    void* mem6 = malloc( 1024 );
    void* mem7 = malloc( 512 );

    free( mem6 );
    free( mem5 );
    free( mem1 );
    free( mem7 );
    free( mem2 );

    void* mem8 = malloc( 4096 );

    free( mem4 );
    free( mem3 );
    free( mem8 );

    return 0;
}
```

3. System Overview and Execution Sequence

3.1. Memory overview

The project maps all code to 0x00000000 – 0x1FFFFFFF in the ARM's ROM space (as the Keil C compiler/ARM assembler does). Additionally, you need to define **multiple dedicated memory spaces** over 0x20001000 – 0x20007FFF in the ARM's **SRAM** space. These dedicated spaces include (1) a heap space, (2) user stack (PSP), (3) SVC stack (MSP), (4) memory control block (MCB) to manage the heap space, and (5) all the SVC-related parameters. See *Table 2*.

Table 2: Memory overview

Address	Size (hex)	Size (B)	Usage
0x20007B00 – 0x20007B7F	0x00000080	128B	(5) System call table used by <code>svc.s</code>
0x20006C00 – 0x20007AFF	0x00000F00	3.8KB	Not used for now
0x20006800 – 0x20006BFF	0x00000400	1KB	(4) Memory Control Block to manage in <code>heap.s</code>
0x20006000 – 0x200067FF	0x00000800	2KB	Not used for now.
0x20005800 – 0x20005FFF	0x00000800	2KB	(3) SVC (handler) stack: used by all other files
0x20005000 – 0x200057FF	0x00000800	2KB	(2) User (thread) stack: used by <code>driver.c</code> <code>stdlib.s</code>
0x20001000 – 0x20004FFF	0x00004000	16KB	(1) Heap space controlled by <code>malloc/free</code>
0x20000000 – 0x20000FFF	0x00001000	4KB	Keil C compiler-reserved global data
0x00000000 – 0x1FFFFFFF	0x20000000	512MB	ROM Space: all code mapped to this space

Since we compile `driver.c` (`driver.keil.c`) in your final submission together with assembly programs, the Keil C compiler automatically reserves `driver.c`-related global data to some space within 0x20000000 – 0x20000FFF, which makes it difficult to start Process Stack Pointer (PSP) exactly at 0x20005800 toward the lower address and to start Master Stack Pointer (MSP) exactly at 0x20006000 toward the lower address. So, it's sufficient to map PSP and MSP around but not exactly at 0x20005800 and 0x20006000, respectively. For the purpose of this memory allocation, you should declare the space as shown in *Listing 2*:

```

Heap_Size      EQU      0x00005000
__heap_base    AREA     HEAP, NOINIT, READWRITE, ALIGN=3
Heap_Mem       SPACE    Heap_Size
__heap_limit

Handler_Stack_Size EQU    0x00000800
Thread_Stack_Size EQU    0x00000800
Thread_Stack_Mem AREA     STACK, NOINIT, READWRITE, ALIGN=3
__initial_user_sp SPACE    Thread_Stack_Size
Handler_Stack_Mem SPACE    Handler_Stack_Size
__initial_sp

```

3.2. Initialization and system call sequences

- (1) **Initialization.** The ARM processor reads the first 8 bytes to set MSP and the next 8 bytes to jump to the `Reset_Handler` routine (as you studied in the class). You don't have to change the original vector table. `Reset_Handler` initializes all the data structures you've developed and finally calls `__main` with *Listing 3*.

Listing 3: The last two instructions in `Reset_Handler` (`startup_TM4C129.s`)

```

LDR    R0, =__main
BX     R0

```

These last two statements are from the original `startup_TM4C129.s`. Then, the `main()` function in `driver.c` is invoked.

- (2) **System calls.** Whenever `main()` calls any of `stdlib` functions including `bzero()`, `strncpy()`, `malloc()`, and `free()`, the control needs to move to `stdlib.s`. In other words, you need to define these function protocols in `stdlib.s`, as shown in *Listing 4*:

Listing 4: The framework of `stdlib.s`

```

AREA |.text|, CODE, READONLY, ALIGN=2
THUMB

EXPORT _bzero
_bzero
; Your code to implement the body of bzero( )
MOV     pc, lr ; Return to main( )

EXPORT _strncpy
_strncpy
; Your code to implement the body of strncpy( )
MOV     pc, lr ; Return to main( )

EXPORT _malloc
_malloc
; Your code to invoke the SVC_Handler routine in startup_TM4C129.s
MOV     pc, lr ; Return to main( )

EXPORT _free
_free
; Your code to invoke the SVC_Handler routine in startup_TM4C129.s
MOV     pc, lr ; Return to main( )

END

```

Among these four functions, you'll implement the entire logic of `bzero()` and `strncpy()` as they may be executed in the user mode. However, the other two functions must be handled as a system call. To do so, you need to write code invoke `SVC_Handler` in `startup_TM4C129.s`. Based on the Linux system call convention, **use R7 to maintain the system call number**. Arguments to a system call should follow ARM Procedure Call Standard (APCS), as summarized in *Table 3*.

Table 3: System Call Parameters

System Call Name	R7	R0	R1
<code>malloc</code>	1	arg0: size	
<code>free</code>	2	arg0: ptr	

`SVC_Handler` must invoke `_systemcall_table_jump` in `svc.s`. This in turn means you must prepare the `svc.s` file to implement `_systemcall_table_jump`. This function initializes the system call table in `_systemcall_table_init` as shown in *Table 4*.

Table 4: System Call Jump Table

Memory address	System Calls	Jump destination
0x20007B08	#2: <code>free()</code>	<code>_kfree</code> in <code>heap.s</code>
0x20007B04	#1: <code>malloc()</code>	<code>_kalloc</code> in <code>heap.s</code>
0x20007B00	#0	Reserved

Listing 5: Entry points to kernel functions imported in `svc.s`

```
IMPORT _kfree
IMPORT _kalloc
```

3.3. Structure of your implementation

Table 5: A summary of software components implemented in this final project

Source files	Functions to implement	Functions/routines to call	Control[1:0]
driver_keil.c	main()	→ _bzero → _strncpy → _malloc → _free	11 User/PSP* ¹
stdlib.s	_bzero: entirely implemented here _strncpy: entirely implemented here _malloc: invokes an SVC _free: invokes an SVC	→ SVC_Handler → SVC_Handler	11 User/PSP* ¹
startup_TM4C129.s	Reset_Handler: SVC_Handler	→ __init → _systemcall_table_init → __main → _systemcall_table_jump	00 PriThr/MSP* ² 00 Handler/MSP* ³
svc.s	_systemcall_table_init: see 3.2.(2) _systemcall_table_jump: see 3.2.(2)	→ _kalloc → _kfree	00 Handler/MSP* ³
heap.s	_kinit: initializes memory control blocks _kalloc: buddy allocation coded _kfree: buddy de-allocation coded		00 Handler/MSP* ³

*3: running under the privileged handler mode, using master stack pointer

4. Buddy Memory Allocation and Test Scenario

In this project, you also need to implement the buddy memory allocation in Thumb-2.

4.1. Algorithms

If you have already taken CSS430: Operating Systems, have your OS textbook in your hand and read Section 10.8.1 Buddy System. Since the CSS ordinary course sequence assumes CSS422 taken before CSS430, here is a copy of Section 10.8.1:

10.8.1 Buddy System

The buddy system allocates memory from a fixed-size segment consisting of physically contiguous pages. Memory is allocated from this segment using a power-of-2 allocator, which satisfies requests in units sized as a power of 2 (4 KB, 8 KB, 16 KB, and so forth). A request in units not appropriately sized is rounded up to the next highest power of 2. For example, a request for 11 KB is satisfied with a 16-KB segment.

Let's consider a simple example. Assume the size of a memory segment is initially 256 KB and the kernel requests 21 KB of memory. The segment is initially divided into two buddies—which we will call A_L and A_R —each 128 KB in size. One of these buddies is further divided into two 64-KB buddies— B_L and B_R . However, the next-highest power of 2 from 21 KB is 32 KB so either B_L or B_R is again divided into two 32-KB buddies, C_L and C_R . One of these buddies is used to satisfy the 21-KB request. This scheme is illustrated in Figure 10.26, where C_L is the segment allocated to the 21-KB request.

An advantage of the buddy system is how quickly adjacent buddies can be combined to form larger segments using a technique known as coalescing. In Figure 10.26, for example, when the kernel releases the C_L unit it was allocated, the system can coalesce C_L and C_R into a 64-KB segment. This segment, B_L , can in turn be coalesced with its buddy B_R to form a 128-KB segment. Ultimately, we can end up with the original 256-KB segment.

The obvious drawback to the buddy system is that rounding up to the next highest power of 2 is very likely to cause fragmentation within allocated segments. For example, a 33-KB request can only be satisfied with a 64-KB segment. In fact, we cannot guarantee that less than 50 percent of the allocated unit will be wasted due to internal fragmentation. In the following section, we explore a memory allocation scheme where no space is lost due to fragmentation.

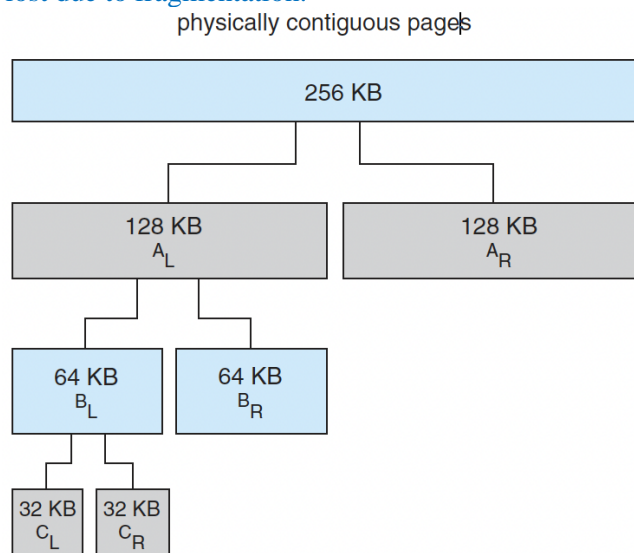

Figure 10.26 Buddy system allocation.

4.2. Implementation over 0x20001000 – 0x20004FFF (Heap space controlled by malloc/free)

As the memory range (**Heap space controlled by malloc/free**) we use is 0x20001000 – 0x20004FFF (See **Table 2**), the entire contiguous size is 16KB. This space will be recursively divided into 2 subspaces of 8KB, each further divided into 2 pieces of 4KB, all the way to 32B. Therefore, one extreme allocates 16KB entirely at once, whereas the other extreme allocates 512 different spaces, each with 32 bytes. To address this finest case, (i.e., handling 512 spaces), we allocate a memory control block (MCB) of 512 entries, each with 2 bytes, in the 1KB space over 0x20006800 – 0x20006BFF (**Memory control block to manage heap space**). Each entry corresponds to a different 32-byte heap space. For instance, MCB entries are defined as:

```
short mcb[512];
```

Then, mcb[0] points to the heap space at 0x20001000, whereas mcb[511] corresponds to 0x20004FE0. However, each mcb[i] does not have to manage only 32 bytes. It can manage up to a contiguous 16KB space. Therefore, each mcb[i] has the size information of a heap space it is currently managing. The size can be 32 bytes to 16KB and thus be represented with 5 to 16 bits, in other words with mcb[i]'s bits #15 - #4. We also use mcb[i]'s LSB, (i.e., bit #0) to indicate if the given heap space is available (= 0) or in use (= 1). **Table 6** shows each mcb[i]'s bit usage.

Table 6: Each mcb entry's bit usage

Bit number	Description
#15 – #4	The heap size this mcb entry is currently managing
#3 – #1	Reserved
#0	0: available, 1: in use

Let's consider a simple memory allocation scenario where main() requests 4KB and thereafter 8KB heap spaces with malloc(4096) and malloc(8192). Based on the buddy system algorithm, this scenario allocates 0x2000100 – 0x20001FFF for the first 4KB request and 0x20003000 – 0x20004FFF for the second 8KB request. **Table 7** shows this allocation. Only mcb[0], mcb[128], and mcb[256] are used to indicate in-use or available spaces. All the other mcb entries are not used yet.

Table 7: Heap space and mcb contents

Heap Address	Memory Availability	MCB	MCB Address	Contents
0x20001000 – 0x20001FFF	4KB in use	mcb[0]	0x20006800	4097 ₁₀ (0x1001)
0x20002000 – 0x20002FFF	4KB available	mcb[128]	0x20006900	4096 ₁₀ (0x1000)
0x20003000 – 0x20003FFF	8KB in use	mcb[256]	0x20006A00	8193 ₁₀ (0x2001)
0x20004000 – 0x20004FFF				

4.3. Implementation

For each implementation of _kinit, _kalloc, and _kfree, refer to **Figure 1** that illustrates how mcb entries are updated.

- (1) **_kinit:** The initialization must write 16384₁₀ (0x4000) onto mcb[0] at 0x20006800-0x20006801, indicating that the entire 16KB space is available. All the other mcb entries from 0x20006802 to 0x20006BFE must be zero-initialized (step 1 in **Figure 1**).
- (2) **_kalloc:** Your implementation must use recursions. When _kalloc(size) is called with a size requested, it should call a helper function, say _ralloc, to recursively choose the left half or the right half of the current range until the requested size fits in a halved range. For instance, in **Figure 1**, the first malloc(4096) call is relayed to _kalloc(4096) that then calls _ralloc(4096, mcb[0], mcb[511]) or _ralloc(4096, 20006800, 20006BFE). See step 2 in **Figure 1**. The _ralloc call finds mcb[0] at 0x20006800 has 16384B (16KB) available, halves it, and chooses the left half by calling itself with _ralloc(4096, mcb[0], mcb[255]) or _ralloc(4096, 20006800, 200069FE). At this time, make sure that the right half managed by mcb[256] at 0x20006A00 must be updated with 8192 as

its available space (step 3 in **Figure 1**). Since the range is still 8192 bytes > 4096 bytes, `_ralloc` chooses the left by calling itself with `_ralloc(4096, mcb[0], mcb[127])` or `_ralloc(4096, 20006800, 200068FE)`. Make sure that the right half managed by `mcb[128]` at `0x2006900` is updated to 4096. The left half in the range between `mcb[0]-mcb[17]` or `0x20006800-200068FF` fits the requested size of 4096. Therefore, `ralloc()` records `409710 (0x1001)` into `mcb[0]` at `0x20006800-0x20006801` (step 4 in **Figure 1**).

The second `malloc(8192)` is handled as follows: `_kalloc(8192)` calls `_ralloc(8192, mcb[0], mcb[511])` or `_ralloc(8192, 20006800, 20006BFE)` (step 5 in **Figure 1**) to choose the right half with `_ralloc(8192, 20006A00, 20006BFE)`, because `mcb[0]` at `0x20006800-0x20006801` has a value of 4097 indicating that the left half (`0x20006800 – 0x200069FE`) is in use. Since `mcb[256]` at `0x20006A00-0x20006A01` is available, `_ralloc` saves 8193 (`0x2001`) there (step 6 in **Figure 1**).

- (3) **_kfree:** Your `_kfree` implementation must also use recursions. The `_kfree(*ptr)` function calls a helper function, `_rfree` (the corresponding `mcb[]`). If `main()` calls `free(0x20001000)`, it is relayed to `_kfree(0x20001000)` that calls `_rfree(mcb[0])` or `_rfree(0x20006800)` to reset its bit #0 from in-use to available (step 7 in **Figure 1**). Then, check its right buddy at `mcb[128]` (or `0x20006900`). If its bit #0 is 0, indicating the availability, zero-reinitialize `mcb[128]` at `0x20006900` and make sure that `mcb[0]` at `0x20006800` shows an availability of 8192 bytes (step 8 in **Figure 1**). Recursively check the buddy at higher layers. So, the next higher layer's buddy is `mcb[256]-mcb[511]` at `0x2006A00-0x2006BFE`. Check `mcb[256]`'s contents, (at `0x20006A00-0x20006A01`). In **Figure 1**, the content is `0x2001`, showing that 8KB is being occupied. Therefore, stop `_kfree`'s recursive calls.

Figure 1: Recursive `_ralloc/_rfree` calls, each updating `mcb` entries

		step 1 _kinit()	step 2 _ralloc(4096, 20006800, 200068FE)	step 3 _ralloc(4096, 20006800, 200068FE)	step 4 _ralloc(4096, 20006800, 200068FE)	step 5 _ralloc(8192, 20006A00, 20006BFE)	step 6 _ralloc(8192, 20006A00, 20006BFE)	step 7 _kfree(20001000)	step 8 recursive _rfree(20006800)
mcb[]	MCB Address								
mcb[0]	0x20006800	0x4000	0x4000	0x2000	0x1001	0x1001	0x1001	0x1000	0x2000
:	:	0x0000	0x0000						
mcb[127]	0x200068FE	0x0000	0x0000

:	:	0x0000	0x0000						
mcb[383]	0x20006AFE	0x0000	0x0000						
mcb[384]	0x20006B00	0x0000	0x0000						
:	:	0x0000	0x0000						
mcb[511]	0x20006BFE	0x0000	0x0000						

4.4. Test Scenario

Looking back to **Listing 1** (`driver.c` code example), you are supposed to verify your Thumb-2 implementation of `malloc()` and `free()` with repetitive system call invocations that allocate/deallocate `mem1 – mem8` spaces. **Figure 2** illustrates how the heap space is allocated and deallocated when you run `driver.c`. Orange indicates allocated spaces and green means de-allocated spaces.

Figure 2: Test scenario and memory allocation

5. Implementation Steps, Timeline, and Submissions

Since it is hard to implement everything in assembly code at once, the final project will take the following two parts. To work on your project, distinguish the following **three versions** of **driver.c** program as shown in **Table 9**. They are all provided and available from Canvas → files → Project → code.

<https://powcoder.com>

Table 9: Provided driver programs

File name	Tasks
driver.c	This is a C program that can be compiled with gcc and executable on Linux. You used this file to understand how the required functions work. You DO NOT need to change this file at all.
driver_cpg.c	This is a C program that should be used for testing and understanding heap.c. The difference from driver.c is: <ul style="list-style-type: none"> - malloc() and free() are renamed to _malloc() and _free(), so that the compiler can use your own implementation of _malloc() and _free(). - printf() are included to verify your implementation.
driver_keil.c	This is a C program that can be compiled with Keil C compiler and executable with your ARM/THUMB-2 assembly code. You will use this file to test stdlib.s implementation in Part 1 toward your midpoint report. You will also use this file to test the final implementation of stdlib.s, heap.s, and svc.s in the Part 2 work. The difference from driver.c is: <ul style="list-style-type: none"> - all stdlib functions bzero(), strncpy(), malloc(), and free() are renamed to _bzero(), _strncpy(), _malloc(), and _free(), so that the compiler can use your own implementation.

5.1. Part 1 toward the midpoint report (due on 2nd class date in week 7)

Part 1 intends to help you understand and develop the following two features:

- (1) **The reset sequence from the assembly language level all the way to main() in C that calls back down to stdlib.s in the assembly language level.**

startup_tm4c129.s → main() in driver_keil.c → stdlib.s

Your actual work on Keil uVision is summarized below in *Table 10*.

Table 10: Keil uVision work toward the midpoint report

Files you will work on	Tasks
startup_tm4c129.s	Revise the Reset_Handler routine as follows: <ul style="list-style-type: none"> - Set up and switch PSP (Process Stack Pointer) - Call __main.
stdlib.s	_bzero and _strncpy: Receive arguments from main(), based on APCS, and complete the entire implementation within stdlib.s . _malloc and _free: Receive arguments from main(), based on APCS, but does nothing by simply returning to main() . You can use the provided <code>stdlib_template.s</code> to implement stdlib.s.

For this task, you need to build your project in Keil uVision.

In Keil uVision, start the debugger and take a memory snap of stringA and stringB after an execution.

(2) Understand and add comments to the C code that implements buddy memory allocation

You can find `heap.c` in Canvas > Files > Project > code. This is a complete implementation of buddy memory allocation in C. *Table 11* summarizes the implementation in Part 1.

Table 11: Linux C programming work toward the midpoint report

Files you will work on	Tasks
driver_cpg.c	No need to change.
heap.c	Add comments to every function In Part 2 section 5.2) <code>kmalloc()</code> , <code>kalloc()</code> , <code>_malloc()</code> , <code>_free()</code> , and <code>_rfree()</code> will be implemented using ARM/Thumb-2 in <code>heap.s</code> .

For this task, you SHOULD NOT use Keil uVision. You only need to compile and run `heap.c` as follow:

```
gcc driver_cpg.c heap.c -o ./a.out
```

```
./a.out
```

Submission Items:

For Part 1, please submit the following materials listed in *Table 12*.

Table 12: Part-1 Submission and Grading

Materials	Remarks	Grade points (out of 25pts)
startup_tm4c129.s	From your Keil uVision project	4pts
stdlib.s	From your Keil uVision project	10pts
Two memory snapshots: stringA and stringB	From your Keil uVision project	4pts
heap.c with detailed comments	No need to write new code, just add comments	5pts
Flow chart to illustrate how heap.c works	Provide clear flow charts (one or more) to show your understanding of the heap.c code	2pts

5.2. Part 2 toward the final report (due on 2nd class date in week 11, i.e., final's week)

Part 2 intends to complete all assembly components using ARM/THUMB-2. Your tasks in Part 2 are summarized below in *Table 13*.

Table 13: Part-2 Work Items

Files you will work on	Tasks
startup_tm4c129.s	Correct the Reset_Handler routine if necessary. Thereafter, add subroutine calls : <ul style="list-style-type: none"> - _kinit: initialization in heap.s - _systemcall_table_init: initialization in svc.s (<i>Table 4</i> in Section 3.2.(2)) Implement the following routine : <ul style="list-style-type: none"> - SVC_Handler: invoke _system_call_table_jump in svc.s
driver_keil.c	No need to change.
stdlib.s	Correct _bzero and _strncpy if necessary. _malloc and _free: Receive arguments from main(), based on APCS and relay each call to SVC_Handler .
svc.s	Refer to Section 3.2.(2). Based on the system call # in R7, jump to the corresponding function through the system call jump table shown in <i>Table 4</i> .
heap.s	Implement the following routines, based on the C implementation in heap.c. _kinit: mcb initialization _kalloc: the entry point to invoke the _ralloc recursive helper function _ralloc: a recursive helper function to allocate a space _kfree: the entry point to invoke the _rfree recursive helper function _rfree: a recursive helper function to free the space and merge the buddy space if possible

Test all your assembly language implementation with **driver_keil.c** on Keil uVision's debugger session. Take all memory snapshots of mcb addresses corresponding to mem1 – mem8 upon their allocation and deallocation.

Submission Items:Please submit the following materials listed in *Table 14*.**Table 14: Part-2 Submission and Grading**

Materials	Remarks	Grade points (out of 75pts)
Your zipped Keil uVision project (47pts)	startup_tm4c129.s (9pts) Reset_Handler SVC_Handler	3pts 6pts
	driver_keil.c (0pt)	0pt (provided code)
	stdlib.s (0pt) _bzero() _strncpy() _malloc() _free()	0pt (provided code) 0pt (provided code) 0pt (provided code) 0pt (provided code)
	svc.s (10pts) _systemcall_table_init _systemcall_table_jump	5pts 5pts
	heap.c (28pts) _kinit _kalloc _kfree	4pts 12pts 12pts
Execution snapshots (16pts)	_strncpy(stringB, stringA, 40); _bzero(stringA, 40); void* mem1 = _malloc(1024); void* mem2 = _malloc(1024); void* mem3 = _malloc(8192); void* mem4 = _malloc(4096); void* mem5 = _malloc(512); void* mem6 = _malloc(1024); void* mem7 = _malloc(512); _free(mem6); _free(mem5); _free(mem1); _free(mem7); _free(mem2); void* mem8 = _malloc(4096); _free(mem4); _free(mem3); _free(mem8);	0pt (provided code) 0pt (provided code) 1pt 1pt 1pt 1pt 1pt 1pt 1pt 1pt 1pt 1pt 1pt 1pt 1pt 1pt 1pt 1pt 1pt
Documentation (12pts)	A two-page summary of your implementation - Narratives o What you implemented. o What was missing. - Any Diagrams (at least one)	5pts 5pts 2pts

5.3. Execution Snapshots

To clarify what you need to turn in execution results, sample snapshots from the key answer are given below. Don't reuse them. **Any reuse of these snapshots below will result in an academic misconduct.**

(a) Midpoint report's stringA and stringB snapshots

The screenshot shows a debugger interface with the following components:

- Registers:** Shows registers R0 through R12, with R0 containing 0x00000000 and R12 containing 0x00000000.
- Disassembly:** Shows assembly instructions for stringA and stringB. The instructions include:

```

      0.083 us 0x00000000 A00B ADD r1,sp,#0x2C
      0.250 us 0x00000000 F7FFFC5B EL.W 0x0000002B8 _strcpy
      26: _strcpy(stringA, 40);
      0x00000000 212B MOV r1,#0x2B
      0x00000000 A00B ADD r0,sp,#0x2C
      0x00000000 F7FFFC5B EL.W 0x0000002A0 _bzero
      27: void* mem1 = _malloc(1024);
      0x00000000 F44F60B0 MOV r0,#0x400
      0x00000000 F7FFFCAD EL.W 0x0000002D8 _malloc
      0x00000000 4604 MOV r4,r0
      28: void* mem2 = _malloc(1024);
      29: void* mem3 = _malloc(1024);
      
```
- Memory:** Shows memory snapshots for stringA and stringB. The snapshots show the contents of the strings in hexadecimal and ASCII format.

6. Final notes

- (1) Follow the final project specification.
 - a. Use the memory spaces exactly specified in this document.
 - b. Use the function and routine names specified in this document.
 - c. Attach the execution results as specified in this document (see Tables 12 and 14).
- (2) Check Canvas→files→Project→code folder for additional materials.
- (3) Start your implementation early and keep up your plan.
